ABSTRACT
In this paper the vibration of a spinning cylindrical shell made of functional graded material is investigated. After a brief introduction of FG materials, by employing higher order theory for shell deformation, constitutive relationships are derived. Next, governing differential equation of spinning cylindrical shell is obtained through utilizing energy method and Hamilton’s principle. Making use of the principle of minimum potential energy, the characteristic equation of natural frequencies is derived. After verification of the results, the effect of changing different parameters such as material grade, geometry of shell and spinning velocity on the natural frequency are examined.

Keywords: Vibration; Functionally graded material; Spinning cylindrical shell; Higher order shear deformation theory

1 INTRODUCTION

THE concept of functionally gradient materials (FGMs) was first introduced in 1984 by a group of materials scientists in Japan when they were in a process of preparing thermal barrier materials [1, 2]. Since then, FGMs have attracted much of the interests as a heat-shielding material. FGMs are made by combining different materials using powder metallurgy methods [3]. They possess property variations in the constituent volume fractions that lead to continuous change in the composition, microstructure, porosity, etc. as well as results in gradients in the mechanical and thermal properties [2, 4-7]. Studies on FGMs have been extensive but are largely confined to analysis of thermal stress and deformation [8-12]. Related to the vibration of cylindrical shells numerous researches were conducted. Many of these studies are for isotropic and composite shells. Arnold and Warburton [10], Ludwig and Krieg [11], Chung [12], Soedel [13], Forsberg [14], Bhimaraddi [15], Soldatos and Hajigeoriou [16], Soldatos [17], Lam and Loy [18], Loy and Lam [19], and Loy, Lam and Shu [20] are among those who have carried out studies on the vibration of cylindrical shells. Nevertheless, associated with the vibration of cylindrical shells made of FG material only one work is reported [21] in which the bases of vibration analysis were on the usage of classical theory. To move one step further on this analysis, in this work the higher order shear deformation theory (HSDT) is employed on the spinning shells which have various applications in the industry.

In this paper, the vibration of a spinning cylindrical shell made of functional graded material (FGM) is investigated. The considered functionally graded material is composed of stainless steel and nickel where the volume fractions follow a power-law distribution. The objective is to study the frequency characteristics, the influence of the constituent volume fractions, and the effects of the configurations of the constituent materials on the natural frequencies. A functionally graded cylindrical shell is essentially an inhomogeneous shell consisting of a mixture of isotropic materials. The analysis of the functionally graded cylindrical shell is carried out using higher order theory for shell deformation and solved using Hamilton’s principle method.

1 FUNCTIONALLY GRADED MATERIALS

One of the most advantages of the FGM over other engineering materials is its superior resistant against harsh temperature condition. The combined material properties of such a material can be expressed as [21]

\[ P_F(T, z) = \sum_{i=1}^{m} P_{mi}(T)V_{mi}(z) \]  

where \( P_F \) can be any effective FGM property, \( P_{mi} \) is a parameter depending on temperature and \( V_{mi} \) is a volume fraction for \( i \)th material. Moreover, \( T \) represents the temperature (°K) and \( z \) is the coordinate along the body thickness. The parameter for each material usually is expressed as [21]

\[ P_{mi}(T) = P_0 \left( \frac{P_1}{T} + 1 + P_2 T + P_3 T^2 + P_4 T^3 \right) \]  

in which \( P_0, P_1, P_2, P_3, \) and \( P_4 \) are some temperature dependent parameters. In order to model the property distribution, according to Voigt model which assumes that the strain is the same in the ceramic and in the metal, the FGM mechanical property is expressed as

\[ P = \sum_{i=1}^{m} V_{bi} P_i \]  

\[ P(z) = P_c V_c + P_m V_m \]  

in which \( P \) is the effective FGM property, indices \( c \) and \( m \), stand for ceramic and metal respectively, and \( V \) represents the FGM volume fraction subjected to the law

\[ V_c + V_m = 1 \]  

For a cylindrical shell with thickness \( h \), the variation of the volume fraction of phases can be expressed according to the following power law in terms of thickness \( z \)

\[ V_{mi} = \left( \frac{2z + h}{h} \right)^N \]  

For the mechanical properties of the cylindrical shell either of following power law models can be used

\[ P(z) = (P_c - P_m) \left( \frac{2z + h}{h} \right)^N + P_m \]  

\[ P(z) = (P_m - P_c) \left( \frac{2z + h}{h} \right)^N + P_c \]  

For example, the Young’s modulus for functionally graded (FG) cylindrical shell with \( N=0.5 \) can be expressed as

\[ E(z) = (E_c - E_m) \left( \frac{2z + h}{h} \right)^{0.5} + E_m \]  

This means that the cylindrical shell at \( z=h/2 \) is completely metal and in the \( z=-h/2 \) it is completely ceramic. In other words, shell starts from inside surface by ceramic material and becomes completely metal at the outside wall.

2 GOVERNING EQUATIONS

Consider a cylindrical spinning shell made of FGM, with length \( L \), radius \( R \), and thickness of \( h \), spinning around its symmetric axis with constant angular velocity of \( \Omega \) (see Fig. 1). In vibration analysis of shell in this work, higher order shear deformation theory is considered. Based on the assumptions prevailing on this theory, differential equations are derived. For a point located somewhere on the spinning shell and referred to the coordinate system shown in Fig. 1, the position and velocity of such point are [22]

\[
\begin{align*}
\vec{r} &= \hat{u} + \hat{v} + \hat{w} \\
\vec{V} &= \hat{\bar{u}} + \hat{\bar{v}} + \hat{\bar{w}} + (\Omega \times \hat{\bar{w}}) + (\Omega \times \hat{\bar{v}})
\end{align*}
\]

where \( i, j \) and \( k \) are unit vectors in the cylindrical coordinates of \( x, \theta \) and \( z \), respectively. Moreover, \( \Omega \) is shell rotational speed, \( u, v \) and \( w \) are displacement components in \( x, \theta \) and \( z \) directions, respectively and \( \hat{\bar{u}}, \hat{\bar{v}}, \hat{\bar{w}} \) are time derivative of displacement components. As it was mentioned, in this study we use the Reddy higher order theory [23] assumptions in which the general form of displacement components are defined as

\[
\begin{align*}
u(x, \theta, z) &= u_0(x, \theta) + z \beta_x(x, \theta) + z^2 \mu_x(x, \theta) + z^3 \psi_x(x, \theta) \\
v(x, \theta, z) &= v_0(x, \theta) + z \beta_\theta(x, \theta) + z^2 \mu_\theta(x, \theta) + z^3 \psi_\theta(x, \theta) \\
w(x, \theta, z) &= w_0(x, \theta)
\end{align*}
\]

in which, \( u_0, v_0, w_0, \beta_x, \beta_\theta, \mu_x, \mu_\theta, \psi_x \), and \( \psi_\theta \) are defined as

\[
\begin{align*}
u_0 &= u(x, \theta, 0, t), & v_0 &= v(x, \theta, 0, t), & w_0 &= w(x, \theta, 0, t) \\
\beta_x &= \left( \frac{\partial u}{\partial z} \right)_{z=0}, & \mu_x &= \left( \frac{\partial^3 u}{\partial z^3} \right)_{z=0}, & \psi_x &= \left( \frac{\partial^4 u}{\partial z^4} \right)_{z=0} \\
\beta_\theta &= \left( \frac{\partial v}{\partial z} \right)_{z=0}, & \mu_\theta &= \left( \frac{\partial^3 v}{\partial z^3} \right)_{z=0}, & \psi_\theta &= \left( \frac{\partial^4 v}{\partial z^4} \right)_{z=0}
\end{align*}
\]

Moreover, based on this theory, we further have

\[
\varepsilon_x = 0 \\
\sigma_{xx}(x, \theta, \pm \frac{h}{2}, t) = \sigma_{EE}(x, \theta, \pm \frac{h}{2}, t) = 0
\]

Since the cylindrical shell has a thin wall, the strain components can be defined as

![Fig. 1 Spinning cylindrical shell, geometry and coordinates.](image-url)
\[
\begin{align*}
\left( \varepsilon_x, \varepsilon_{x\theta} \right) &= \left( \varepsilon_x^0, \varepsilon_{x\theta}^0 \right) + z \left( k_x^v, k_{x\theta}^v \right) + z^2 \left( k_x^v, k_{x\theta}^v \right) \\
\left( \varepsilon_{R\theta}, \varepsilon_{R\theta\theta} \right) &= \left( \varepsilon_{R\theta}^0, \varepsilon_{R\theta\theta}^0 \right) + z^2 \left( k_{R\theta}^v, k_{R\theta\theta}^v \right)
\end{align*}
\]

where

\[
\begin{align*}
\left( k_x^v, k_{x\theta}^v \right) &= \left( \frac{\partial \beta_x}{\partial x}, \frac{\partial \beta_x}{\partial \theta} \right) + \frac{\beta_x + \frac{\partial w_x}{R\theta}}{R\theta} \left( \frac{\partial^2 \beta_x}{\partial x^2}, \frac{\partial^2 \beta_x}{\partial x \partial \theta} \right) + \frac{4}{h} \left( \frac{\beta_x + \frac{\partial w_x}{R\theta}}{R\theta} \right) \left( k_{x\theta}^v, k_{x\theta\theta}^v \right) = \frac{4}{3h^2} \left( \frac{\beta_x + \frac{\partial w_x}{R\theta}}{R\theta} \right) \left( k_{x\theta}^v, k_{x\theta\theta}^v \right)
\end{align*}
\]

Furthermore, by employing Hook’s law one can easily calculate the following forces (normal and shear) and moments (bending and torsional) all per unit of length as

\[
\begin{align*}
(N_x, N_{x\theta}, N_{x\theta\theta}) &= \int_{-h/2}^{h/2} \left( \sigma_x, \sigma_{x\theta}, \sigma_{x\theta\theta} \right) \mathrm{d}z \\
(M_x, M_{x\theta}, M_{x\theta\theta}) &= \int_{-h/2}^{h/2} \left( \sigma_x, \sigma_{x\theta}, \sigma_{x\theta\theta} \right) z \mathrm{d}z \\
(P_x, P_{x\theta}, P_{x\theta\theta}) &= \int_{-h/2}^{h/2} \left( \sigma_x, \sigma_{x\theta}, \sigma_{x\theta\theta} \right) z^2 \mathrm{d}z \\
(Q_x, S_x) &= \int_{-h/2}^{h/2} \sigma_{x\theta} (1, z^2) \mathrm{d}z \\
(Q_{x\theta}, S_{x\theta}) &= \int_{-h/2}^{h/2} \sigma_{x\theta} (1, z^2) \mathrm{d}z
\end{align*}
\]

in which \(N_i, M_i, P_i, Q_i\) and \(S_i\) are system of forces or moments and can be represented in matrix form as

\[
\{N\} = [S] \{\varepsilon\}
\]

in which

\[
\begin{align*}
[S] &= \begin{bmatrix}
N_x & N_{x\theta} & N_{x\theta\theta} & M_x & M_{x\theta} & M_{x\theta\theta} & P_x & P_{x\theta} & P_{x\theta\theta}
\end{bmatrix} \\
\{\varepsilon\} &= \begin{bmatrix}
\varepsilon_x & \varepsilon_{x\theta} & \varepsilon_{x\theta\theta} & k_x & k_{x\theta} & k_{x\theta\theta} & k_x^2 & k_{x\theta}^2 & k_{x\theta\theta}^2
\end{bmatrix}
\end{align*}
\]

© 2009 IAU, Arak Branch
Furthermore, related to shear terms in the Hook’s law, one can obtain the following shear forces and bending moments due to shear forces (all per unit of length) as

\[
\mathbf{T} = \mathbf{X} \mathbf{\{ \varepsilon_s \}}
\]

in which

\[
\begin{bmatrix}
A_{11} & A_{12} & 0 & B_{11} & B_{12} & 0 & E_{11} & E_{12} & 0 \\
A_{12} & A_{22} & 0 & B_{12} & B_{22} & 0 & E_{12} & E_{22} & 0 \\
0 & 0 & A_{66} & 0 & 0 & B_{66} & 0 & 0 & E_{66} \\
B_{11} & B_{12} & 0 & D_{11} & D_{12} & 0 & F_{11} & F_{12} & 0 \\
B_{12} & B_{22} & 0 & D_{12} & D_{22} & 0 & F_{12} & F_{22} & 0 \\
0 & 0 & B_{66} & 0 & 0 & D_{66} & 0 & 0 & F_{66} \\
E_{11} & E_{12} & 0 & F_{11} & F_{12} & 0 & H_{11} & H_{12} & 0 \\
E_{12} & E_{22} & 0 & F_{12} & F_{22} & 0 & H_{12} & H_{22} & 0 \\
0 & 0 & E_{66} & 0 & 0 & F_{66} & 0 & 0 & H_{66} \\
\end{bmatrix}
\]

It should be mentioned that for the isotropic materials the elements of \(Q_{ij}\) (i,j = 1,2,6) matrix turned to be as

\[
Q_{11} = Q_{22} = \frac{E}{1 - \nu^2} \\
Q_{12} = \frac{\nu E}{1 - \nu^2} \\
Q_{44} = Q_{55} = Q_{66} = \frac{E}{2 + 2\nu}
\]

### 2.1 Boundary conditions

In this study the boundary condition of both ends are taken to be simply supported. Based on this type of boundary condition, following admissible displacement field for any point on the mid-plane surface is given by

\[
\begin{align*}
\mathbf{u}_0(x, \theta, t) &= A \sin \frac{m \pi x}{L} \cos (n \theta + \omega t) \\
\mathbf{v}_0(x, \theta, t) &= B \cos \frac{m \pi x}{L} \sin (n \theta + \omega t) \\
\mathbf{w}_0(x, \theta, t) &= C \cos \frac{m \pi x}{L} \cos (n \theta + \omega t)
\end{align*}
\]
\[ \beta_x(x, \theta, t) = D \sin \frac{m \pi x}{L} \cos (n \theta + \omega t) \]

\[ \beta_\theta(x, \theta, t) = E \cos \frac{m \pi x}{L} \sin (n \theta + \omega t) \]

In Eq. (19), the coefficients \( A, B, C, D, \) and \( E \) represent the magnitude of the vibration amplitude in the aforementioned directions. By employing energy method i.e., defining the kinetic energy, internal energy (due to existing stresses) and work done by external forces of the system and imposing the Hamilton principle, differential equation of the motion can be obtained. The variational form of the functional (potential energy) is expressed as

\[
\frac{\delta}{\delta F_1} \left( T - U + W \right) dt = 0
\]

in which \( T, U \) and \( W \) represent the kinetic energy, internal energy and work done by external forces, respectively. For the geometry under consideration, i.e. cylindrical shell, the kinetic energy is defined by

\[ T = \frac{1}{2} \rho h \int_0^l \int_0^{2\pi} \hat{V} \cdot \ddot{V} R \, d\theta \, dx \]

in which \( \rho_a = \rho \), i.e., \( \rho \) is the density per unit length. Substituting Eq. (8) into Eq. (21) satisfy the following equation

\[ T = \frac{1}{2} \rho h \int_0^l \int_0^{2\pi} \left( u'^2 + v'^2 + w'^2 + 2\Omega (\nu v' - w v') + \Omega^2 (v^2 + w^2) \right) R \, d\theta \, dx \]

Related to the internal energy, we break it into two parts; i.e. strain energy due to centrifugal force \((\hat{N}_\theta = \rho \hat{\omega}^2 \Omega^2 R^2)\) which is shown by \( U_h \) and defined as [22]

\[ U_h = \frac{1}{2} \int_0^l \int_0^{2\pi} \left\{ \frac{1}{R} \left( \hat{\omega} \frac{\partial u}{\partial \theta} \right)^2 + \left[ \frac{1}{R} \left( \hat{\omega} \frac{\partial v}{\partial \theta} + w \right) \right]^2 + \left[ \frac{1}{R} \left( \hat{\omega} \frac{\partial w}{\partial \theta} - v \right) \right]^2 \right\} R \, d\theta \, dx \]

and shell strain energy due to internal stresses shown by \( U_c \) is defined by

\[ U_c = \frac{1}{2} \int_0^l \int_0^{2\pi} \epsilon^T \sigma [\epsilon] R \, d\theta \, dx \]

After substituting Eqs. (22-24) into Eq. (20), the equations of motion is obtained

\[
\begin{bmatrix}
C_{11} & C_{12} & C_{13} & C_{14} & C_{15} \\
C_{21} & C_{22} & C_{23} & C_{24} & C_{25} \\
C_{31} & C_{32} & C_{33} & C_{34} & C_{35} \\
C_{41} & C_{42} & C_{43} & C_{44} & C_{45} \\
C_{51} & C_{52} & C_{53} & C_{54} & C_{55}
\end{bmatrix}
\begin{bmatrix}
A \\
B \\
C \\
D \\
E
\end{bmatrix}
= 0
\]

Now by setting the determinant of above linear algebraic equation to zero, the characteristic equation of natural frequencies which is an equation of order tenth in \( \omega \) is obtained

\[ \lambda_x \omega^{10} + \lambda_1 \omega^9 + \lambda_2 \omega^8 + \lambda_3 \omega^7 + \lambda_4 \omega^6 + \lambda_5 \omega^5 + \lambda_6 \omega^4 + \lambda_7 \omega^3 + \lambda_8 \omega^2 + \lambda_9 \omega + \lambda_{10} = 0 \]

© 2009 IAU, Arak Branch
where \( \lambda_i \) (i=0,1,...10) in Eq. (26) are all functions of elements of \([C]\) matrix.

## 3 RESULTS AND DISCUSSIONS

By solving Eq. (26), natural frequencies of spinning cylindrical shell can be determined. Table 1 lists the value of different parameters such as \( E, \nu \) and \( \rho \) of stainless steel and nickel part of the FG material. The result of solving Eq. (26) i.e. natural frequency vs. wave number \( n \), for different values of volume fraction power \( N \), \( L/R=20, h/R=0.05, \Omega=50 \) (rps) and \( m=1 \) is listed in Table 2. It should be mentioned that the values under \( N^{0.5} \) and \( N^0 \) columns on this table represent the natural frequency of the cylindrical shell made of only stainless steel or only nickel, respectively. If we just change the value of \( h/R \) from 0.05 to 0.002 which means for reducing the thickness 25 times less and keeping the other parameters unchanged, the results of natural frequencies vs. wave number are listed in Table 3. The pictorial variations of the natural frequencies given in Tables 2-3 are shown in Figs. 2-3. As it is seen from Tables 2-3, the variation of natural frequency for different values of volume fraction from 0.5 to 20, has only a discrepancy of about 2.3% and the highest value for the natural frequency in this range belongs to the case of isotropic state made of stainless steel (\( N^0=0 \)). The lowest value for the natural frequency in this range belongs to the case of isotropic state made of ceramic (\( N^{0.5}=0 \)). It can be verified that for the FG material of first kind, by increasing the value of \( N \), the natural frequency approaches to the case of \( N^0 \) i.e. an isotropic media made of nickel which is an indication of reduction of natural frequency. Referred to Fig. 3, it can be noticed that for a thin cylindrical shell the natural frequency has its minimum value for \( n=2 \) and 3, a condition which compared to Fig. 2 is created due to thinness (\( h/R<1 \)) of the shell.

Now, let us calculate the values of the natural frequency while \( h/R \) is changing for different values of volume fraction under condition of \( L/R=20, \Omega=50 \) (rps) and \( m=1 \). The result of this variation is given in Table 4. Moreover, the given results in Table 4 are converted into different curves depicted in Fig. 4.

As can be seen from Fig. 4, the natural frequency increases more or less in a linear fashion up to \( h/R = 0.024 \) and then it decreases a bit and remains unchanged afterwards. This trend is observed for all sort of different FG materials. In a parallel analysis, the values of the natural frequency while \( L/R \) is changing for different values of volume fraction and wave number under condition of \( h/R = 0.002, \Omega = 50 \) (rps) and \( m = 1 \). The result of such analysis is given in Table 5 and also depicted in Fig. 5. Related to Figs. 4 and 5, one can realize that the natural frequency of a short cylindrical shell of FG material is higher than the longer one. In other words, by reducing the value of \( L/R \), the natural frequency of a cylindrical shell increases. By setting the value of \( L/R = 20, h/R = 0.05, n = 1, m = 1 \), the values of natural frequency of cylindrical shell for different FG materials are obtained while the spinning speed of the shell...
changes. The result of such calculation is listed in Table 6. By close examination of numbers in any specific column in this table, one can deduce that little variations exist. In other words, any variation in the spinning speed has insignificant effect on the natural frequency of the cylindrical shell made of FG material. This finding is consistent with the fact that the natural frequency is not a function of excitation frequency but rather function of intrinsic properties such as structural mass and stiffness of the body. To validate the accuracy of our analysis, the results of first ten natural frequencies for simply supported cylindrical shells based on higher order shear deformation theory (HSDT) and classical shell theory (CST) are compared with Loy et al. [21], when $L/R=20$, $h/R=0.01$, $\nu=0.3$, (see Table 7). Another comparison is made with work of Arnold and Warburton [10] for two specific natural frequencies but different wave numbers (see Table 8).

In both of these cases \( \zeta = \omega R \sqrt{\frac{1-v^2}{\rho E}} \). While vibrating analysis of simply supported FG cylindrical shells composed of stainless steel and nickel with its properties changing in the thickness-wise direction according to a volume fraction power-law, let us consider the effect of the changing the constituent volume fractions \( V_f \) and see how does it affect the FGM configuration. This can be done by varying-simultaneously-the volume fractions of the stainless steel and nickel, which is taking care of by changing the value of the power-law exponent \( N \). The effects on the FGM configuration are studied by studying the frequencies of two FG cylindrical shells i.e. Type-I FG cylindrical shell and Type-II FG cylindrical shell. Type-I FG cylindrical shell has nickel on its inner surface and stainless steel on its outer surface and Type-II FG cylindrical shell has stainless steel on its inner surface and nickel on its outer surface. Figs. 6 and 7 show the variations of the volume fractions \( V_f \) of nickel and stainless steel, in the thickness-wise direction \( z \) for Type-I and Type-II FG cylindrical shells, respectively.

Fig. 6
Variation of volume fraction of nickel in the thickness-wise direction z, Type I.

Fig. 7
Variation of volume fraction of Stainless Steel in the thickness-wise direction z, Type II.

The influence of the value of N, which affects the constituent volume fraction, can be seen from the tables. As N increased, the natural frequencies decreased. The decreased in the natural frequencies from N=1 to N=15 is about 2.3% at n=1 and about 2.4% at n=10. The natural frequencies approach those of NSS when N is small and they approach those of NN when N is large.

4 CONCLUSIONS

Based on the higher order shear deformation theory as well as calculated and depicted results of a spinning cylindrical shell made of different types of FG materials it can be concluded that:
(i). Variation on the shell rotational speed has no effect on the value of the natural frequency.
(ii). The natural frequency of short cylindrical shell is higher than the long one, having all other parameters the same.
(iii). The natural frequency of thick cylindrical shell is higher than the thin one, having all other parameters the same.
(iv). For the FG material of the first kind, by increasing the value of volume fraction $N$, the natural frequency approaches to the case of $N=0$, i.e. an isotropic media made of nickel. In other words, natural frequency decreases by increasing $N$.
(v). The least value for the natural frequency occurs at $n=2$ and $h/R \leq 0.01$.
