ABSTRACT
This paper deals with the reflection and transmission of elastic waves from imperfect interface separating a micropolar elastic solid half-space and a fluid saturated porous solid half-space. Longitudinal and transverse waves impinge obliquely at the interface. Amplitude ratios of various reflected and transmitted waves are obtained and computed numerically for a specific model and results obtained are depicted graphically with angle of incidence of incident waves. It is found that these amplitude ratios depend on angle of incidence of the incident wave, imperfect boundary and material properties of half-spaces. From the present study, a special case when fluid saturated porous half-space reduces to empty porous solid is also deduced and discussed graphically.

Keywords: Porous solid; Micro polar elastic solid; Reflection; Transmission; Longitudinal wave; Transverse wave; Amplitude ratios; Stiffness.

1 INTRODUCTION
Most of natural and man-made materials, including engineering, geological and biological media, possess a microstructure. The ordinary classical theory of elasticity fails to describe the microstructure of the material. To overcome this problem, Eringen and Suhubi [10] considered the microstructure of the material and they showed that the motion in a granular structure material is characterized not by a displacement vector but also by a rotation vector. Gautheir [12] found aluminum-epoxy composite to be a micro polar material. Many problems of waves and vibrations have been discussed in micro polar elastic solid by several researchers. Some of them are Parfitt and Eringen [23], Tomar and Gogna [26], Tomar and Kumar [27], Singh and Kumar [24], Kumar and Barak [18] etc. On the other side, Brown [4] and de Boer and Ehlers [7-8] developed an interesting theory for porous medium having all constituents to be incompressible. Based on this theory, many researchers like de Boer and Liu [5], Liu [21], de Boer and Didwania [6], Tajuddin and Hussaini [25], Kumar and Hundal [16], Kumari [19], Madan et al. [22], Kumar et al. [14-15] etc. studied some problems of wave propagation in fluid saturated incompressible porous media. Elastic waves propagation in fluid saturated porous media has its importance in various fields such as soil dynamics, hydrology, seismology, earthquake engineering and geophysics. Imperfect interface considered in this problem means that the stress components are continuous and small displacement field is not. The values of the interface parameters depend upon the material properties of the medium. Recently, using the imperfect conditions at

the interface, Kumar and Chawla [17], Kumari [20], Kaliraman [13], Barak and Kaliraman [1-2-3] etc. studied the various types of wave problems.

Using the theory of de Boer and Ehlers [8] for fluid saturated porous medium and Eringen [11] for micro polar elastic solid, the reflection and transmission phenomenon of longitudinal and transverse waves at an imperfect interface between micro polar elastic solid half-space and fluid saturated porous solid half-space is studied. A special case when fluid saturated porous solid half-space reduces to empty porous solid half-space has been deduced and discussed. Amplitudes ratios for various reflected and transmitted waves are computed for a particular model and depicted with help of graphs and discussed accordingly. The model which is considered here is assumed to exist in the oceanic crust part of the Earth and the propagation of wave through such a model will be of great use in the fields which are related to Earth sciences.

2 FORMULATION OF THE PROBLEM

Consider a two-dimensional problem by taking the z-axis pointing into the lower half-space and the plane interface \( z = 0 \) separating the fluid saturated porous solid half-space \( M_1[z > 0] \) and micropolar elastic solid half-space \( M_2[z < 0] \). A longitudinal wave or transverse wave propagates through the medium \( M_1 \) and incident at the plane \( z = 0 \) and making an angle \( \theta_0 \) with normal to the surface. Corresponding to incident longitudinal or transverse wave, we get two reflected waves in the medium \( M_1 \) and three transmitted waves in medium \( M_2 \). See Fig. 1.

3 BASIC EQUATIONS AND CONSTITUTIVE RELATIONS

3.1 For medium \( M_2 \) (Micro polar elastic solid)

The equation of motion in micro polar elastic medium are given by Eringen [11] as:

\[
\left(c_i^2 + c_3^2\right)\nabla^2 \phi = \frac{\partial^2 \phi}{\partial t^2} \\
\frac{\partial^2 U}{\partial t^2}
\]

\[
\left(c_i^2 + c_3^2\right)\nabla^2 U + c_3^2 \nabla \times \Phi = \frac{\partial^2 U}{\partial t^2}
\]

\[
\left(c_i^2 \nabla^2 - 2 \alpha_0^2\right) \Phi + \omega_0^2 \nabla \times \vec{U} = \frac{\partial^2 \Phi}{\partial t^2}
\]

where
\[ c_1^2 = \frac{\lambda + 2\mu}{\rho}; c_2^2 = \frac{\mu}{\rho}; c_3^2 = \frac{\kappa}{\rho}; \omega_j^2 = \frac{\kappa}{\rho j} \]  

(4)

Parfitt and Eringen [23] have shown that Eq. (1) corresponds to longitudinal wave propagating with velocity \( \vec{v}_l \), given by \( \vec{v}_l^2 = c_1^2 + c_3^2 \) and Eqs. (2)-(3) are coupled equations in vector potential \( \vec{U} \) and \( \Phi \) and these correspond to coupled transverse and micro-rotation waves. If \( \frac{\omega_j^2}{\omega_0^2} > 2 \), there exist two sets of coupled-wave propagating with velocities \( \frac{1}{\lambda_2} \) and \( \frac{1}{\lambda_3} \); where

\[ \lambda_2^2 = \frac{1}{2}[B - \sqrt{B^2 - 4C}], \quad \lambda_3^2 = \frac{1}{2}[B + \sqrt{B^2 - 4C}] \]  

(5)

where,

\[ B = q \left( \frac{p - 2}{\omega^2} \right) + \frac{1}{c_2^2 + c_3^2}; \quad C = \left( \frac{1}{c_1^2} - \frac{2q}{\omega^2} \right) \left( \frac{1}{c_2^2 + c_3^2} \right) \]  

\[ p = \frac{\kappa}{\mu + \kappa}; \quad q = \frac{\kappa}{\gamma} \]  

(6)

Considering a two-dimensional problem by taking the following components of displacement and micro-rotation as:

\[ \vec{u} = (u, 0, w) \quad \text{and} \quad \Phi = (0, \Phi_2, 0) \]  

(7)

where,

\[ u = \frac{\partial \phi}{\partial x} - \frac{\partial \psi}{\partial z}; \quad w = \frac{\partial \phi}{\partial z} + \frac{\partial \psi}{\partial x} \]  

(8)

and components of stresses are as under

\[ t_{xx} = (\psi + 2\mu + \kappa) \frac{\partial^2 \phi}{\partial z^2} + \lambda \frac{\partial^2 \phi}{\partial x^2} + (2\mu + \kappa) \frac{\partial^2 \psi}{\partial x \partial z} \]  

\[ t_{xz} = (2\mu + \kappa) \frac{\partial^2 \phi}{\partial x \partial z} - (\mu + \kappa) \frac{\partial^2 \psi}{\partial z^2} + \mu \frac{\partial^2 \psi}{\partial x^2} - \kappa \Phi_2 \]  

\[ m_{\psi z} = \gamma \frac{\partial \Phi_2}{\partial z} \]  

(11)

3.2 For medium \( M_1 \) (Fluid saturated incompressible porous solid half-space)

Following de Boer and Ehlers [8], the governing equations in a fluid-saturated incompressible porous medium are

\[ \text{div}(\eta \vec{x}_s + \eta^T \vec{x}_s) = 0 \]  

(12)

\[ \text{div}T_{\psi} - \eta^T \text{grad} p + \rho^T (b - \vec{x}_s) - P_{\psi} = 0 \]  

(13)
\[
\text{div} T_E^F - \eta^F \text{grad} p + \rho^F (b - \vec{x}_F) + P_E^F = 0
\]
(14)

where \(\vec{x}_i\) and \(\vec{x}_i\) (i = S, F) denote the velocities and accelerations, respectively of solid (S) and fluid (F) phases of the porous aggregate and \(p\) is the effective pore pressure of the incompressible pore fluid. \(\rho^S\) and \(\rho^F\) are the densities of the solid and fluid phases respectively and \(b\) is the body force per unit volume. \(T_E^S\) and \(T_E^F\) are the effective stress in the solid and fluid phase respectively. \(P_E^F\) is the effective quantity of momentum supply and \(\eta^S\) and \(\eta^F\) are the volume fractions satisfying

\[
\eta^S + \eta^F = 1
\]
(15)

If \(u_S\) and \(u_F\) are the displacement vectors for solid and fluid phases, then

\[
\vec{x}_S = \vec{\dot{u}}_S ; \vec{x}_S = \vec{\ddot{u}}_S ; \vec{x}_F = \vec{\dot{u}}_F ; \vec{x}_F = \vec{\ddot{u}}_F
\]
(16)

The constitutive equations for linear isotropic, elastic incompressible porous medium are given by de Boer, Ehlers and Liu [9] as:

\[
T_E^S = 2\mu^S E_S + \lambda^S (E_S J) I
\]
(17)

\[
T_E^F = 0
\]
(18)

\[
T_E^F = -S_v (\vec{\dot{u}}_F - \vec{\ddot{u}}_S)
\]
(19)

where \(\lambda^S\) and \(\mu^S\) are the macroscopic Lame’s parameters of the porous solid and \(E_S\) is the linearized Lagrangian strain tensor defined as:

\[
E_S = \frac{1}{2} \left( \text{grad} u_S + \text{grad'} u_S \right)
\]
(20)

In the case of isotropic permeability, the tensor \(S_v\) describing the coupled interaction between the solid and fluid is given by de Boer and Ehlers [8] as:

\[
S_v = \frac{(\eta^F)^2}{K^F} \gamma^{FR} I
\]
(21)

where \(\gamma^{FR}\) is the specific weight of the fluid and \(K^F\) is the Darcy’s permeability coefficient of the porous medium. Making the use of (16) in Eqs. (12)-(14), and with the help of (17)-(20), we obtain

\[
\text{div}\left(\eta^S \vec{\dot{u}}_S + \eta^F \vec{\dot{u}}_F\right) = 0
\]
(22)

\[
(\lambda^S + \mu^S) \text{grad} u_S + \mu^S \text{grad} u_S - \eta^S \text{grad} p + \rho^S (b - \vec{\ddot{u}}_S) + S_v (\vec{\dot{u}}_F - \vec{\ddot{u}}_S) = 0
\]
(23)

\[
-\eta^F \text{grad} p + \rho^F (b - \vec{\ddot{u}}_F) - S_v (\vec{\dot{u}}_F - \vec{\ddot{u}}_S) = 0
\]
(24)

For the two dimensional problem, we assume the displacement vector \(u_i\) (i = F, S) as:
\[ u_i = (u', 0, w') \text{ where } i = F, S \quad (25) \]

Eqs. (22) - (24) with the help of Eq. (25) in absence of body forces take the form

\[
\eta^s \left[ \frac{\partial^2 u^s}{\partial x \partial t} + \frac{\partial^2 w^s}{\partial z \partial t} \right] + \eta^f \left[ \frac{\partial^2 u^f}{\partial x \partial t} + \frac{\partial^2 w^f}{\partial z \partial t} \right] = 0 \quad (26)
\]

\[
\eta^f \frac{\partial p}{\partial x} + \rho^f \frac{\partial^2 u^f}{\partial t^2} + S_v \left[ \frac{\partial u^f}{\partial t} - \frac{\partial u^s}{\partial t} \right] = 0 \quad (27)
\]

\[
\eta^f \frac{\partial p}{\partial z} + \rho^f \frac{\partial^2 w^f}{\partial t^2} + S_v \left[ \frac{\partial w^f}{\partial t} - \frac{\partial w^s}{\partial t} \right] = 0 \quad (28)
\]

\[
(\lambda^s + \mu^s) \frac{\partial \theta^s}{\partial x} + \mu^s \nabla^2 u^s - \eta^s \frac{\partial p}{\partial x} - \rho^s \frac{\partial^2 u^s}{\partial t^2} + S_v \left[ \frac{\partial u^f}{\partial t} - \frac{\partial u^s}{\partial t} \right] = 0 \quad (29)
\]

\[
(\lambda^s + \mu^s) \frac{\partial \theta^s}{\partial z} + \mu^s \nabla^2 w^s - \eta^s \frac{\partial p}{\partial z} - \rho^s \frac{\partial^2 w^s}{\partial t^2} + S_v \left[ \frac{\partial w^f}{\partial t} - \frac{\partial w^s}{\partial t} \right] = 0 \quad (30)
\]

where,

\[
\theta^s = \frac{\partial (u^s)}{\partial x} + \frac{\partial (w^s)}{\partial z} \quad (31)
\]

and

\[
\nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial z^2} \quad (32)
\]

Also, \( t^{ss}_{xx} \) and \( t^{ss}_{zx} \) the normal and tangential stresses in the solid phase are as under

\[
t^{ss}_{xx} = \lambda^s \left( \frac{\partial u^s}{\partial x} + \frac{\partial w^s}{\partial z} \right) + 2\mu^s \frac{\partial w^s}{\partial z} \quad (33)
\]

\[
t^{ss}_{zx} = \mu^s \left( \frac{\partial u^s}{\partial z} + \frac{\partial w^s}{\partial x} \right) \quad (34)
\]

The displacement components \( u^j \) and \( w^j \) are related to the dimensional potential \( \phi^j \) and \( \psi^j \) as:

\[
u^j = \frac{\partial \phi^j}{\partial x} + \frac{\partial \psi^j}{\partial z} \quad ; \quad w^j = \frac{\partial \phi^j}{\partial z} - \frac{\partial \psi^j}{\partial x} \quad ; \quad j = S, F \quad (35)
\]

Using Eq. (35) in Eqs. (26)-(30), we obtain the following equations determining \( \phi^s, \phi^f, \psi^s, \psi^f \) and \( p \) as:
\[
\begin{align*}
\n\n\frac{\nabla^2 \phi^s}{C_i^2} - \frac{1}{C_i^2} \frac{\partial^2 \phi^s}{\partial t^2} - \frac{S_v}{\left( \lambda^s + 2\mu^s \right) \left( \eta^p \right)^2} \frac{\partial \phi^p}{\partial t} &= 0 \\
\phi^p &= -\frac{\eta^s}{\eta^p} \phi^s \\
\mu^s \nabla^2 \psi^s - \rho^s \frac{\partial^2 \psi^s}{\partial t^2} + S_v \left[ \frac{\partial \psi^p}{\partial t} - \frac{\partial \psi^s}{\partial t} \right] &= 0 \\
\rho^p \frac{\partial^2 \psi^p}{\partial t^2} + S_v \left[ \frac{\partial \psi^p}{\partial t} - \frac{\partial \psi^s}{\partial t} \right] &= 0 \\
\left( \eta^p \right)^3 p - \eta^s \rho^s \frac{\partial^2 \phi^s}{\partial t^2} = 0
\end{align*}
\]

where,
\[
C_i = \sqrt{\frac{\left( \eta^p \right)^3 \left( \lambda^s + 2\mu^s \right)}{\left( \eta^p \right)^2 \rho^s + \left( \eta^p \right)^2 \rho^p}}
\]

Assuming the solution of the system of Eqs. (36)-(40) in the form
\[
(\phi^s, \phi^p, \psi^s, \psi^p, p) = (\phi^s_0, \psi^s_0, \psi^p_0, p_0) \exp(i\omega t)
\]

where \(\omega\) is the complex circular frequency.

Making the use of Eq. (42) in Eqs. (36)-(40), we obtain
\[
\left[ \nabla^2 + \frac{\omega^2}{C_i^2} \frac{i \omega S_v}{\left( \lambda^s + 2\mu^s \right) \left( \eta^p \right)^2} \right] \phi^s = 0
\]
\[
\left[ \mu^s \nabla^2 + \rho^s \omega^2 - i \omega S_v \right] \psi^s = -i \omega S_v \psi^p
\]
\[
\left[ -\omega^2 \rho^p + i \omega S_v \right] \psi^p = 0
\]
\[
\left( \eta^p \right)^3 p + \eta^s \rho^p \omega^2 \phi^s - i \omega S_v \phi^p = 0
\]
\[
\phi^p = -\frac{\eta^s}{\eta^p} \phi^s
\]

Eq. (43) corresponds to longitudinal wave propagating with velocity \(v_1\), given by
\[
v_1^2 = \frac{1}{G_1}
\]

© 2018 IAU, Arak Branch
where,

$$G_1 = \left[ \frac{1}{C_1^2} - \frac{iS_i}{\omega (\lambda^i + 2\mu^i)(\eta^f)^2} \right]$$  \hspace{1cm} (49)$$

From Eqs. (44) and (45), we obtain

$$\left[ \nabla^2 + \frac{\omega^2}{v_s^2} \right] \psi_i^s = 0$$  \hspace{1cm} (50)$$

Eq. (50) corresponds to transverse wave propagating with velocity $v_2$, given by $v_2^2 = \frac{1}{G_2}$, where

$$G_2 = \left[ \frac{\rho^s}{\mu^s} - \frac{iS_i}{\mu^s (\rho^s \omega^2 + i\sigma S_i)} - \frac{S_i^2}{\mu^s (\rho^s \omega^2 + i\sigma S_i)} \right]$$  \hspace{1cm} (51)$$

4 SOLUTION OF THE GOVERNING EQUATIONS

For medium $M_2$, let us consider

$$\phi = B_2 \exp \left[ i \delta_1 \left( x \sin \bar{\theta}_1 - z \cos \bar{\theta}_1 \right) + i \bar{\alpha} \bar{t} \right]$$  \hspace{1cm} (52)$$

$$\psi = B_2 \exp \left[ i \delta_2 \left( x \sin \bar{\theta}_2 - z \cos \bar{\theta}_2 \right) + i \bar{\alpha} \bar{t} \right] + B_3 \exp \left[ i \delta_3 \left( x \sin \bar{\theta}_3 - z \cos \bar{\theta}_3 \right) + i \bar{\alpha} \bar{t} \right]$$  \hspace{1cm} (53)$$

$$\Phi_2 = EB_2 \exp \left[ i \delta_2 \left( x \sin \bar{\theta}_2 - z \cos \bar{\theta}_2 \right) + i \bar{\alpha} \bar{t} \right] + FB_3 \exp \left[ i \delta_3 \left( x \sin \bar{\theta}_3 - z \cos \bar{\theta}_3 \right) + i \bar{\alpha} \bar{t} \right]$$  \hspace{1cm} (54)$$

where

$$E = \frac{\delta_2^2 \left( \delta_2^2 - \frac{\omega^2}{(c_2^2 + c_4^2)} + pq \right)}{\text{deno.}}$$  \hspace{1cm} (55)$$

$$F = \frac{\delta_3^2 \left( \delta_3^2 - \frac{\omega^2}{(c_3^2 + c_4^2)} + pq \right)}{\text{deno.}}$$  \hspace{1cm} (56)$$

and

$$\text{deno} = p \left( 2q - \frac{\omega^2}{c_4^2} \right); \hspace{1cm} \delta_2^2 = \lambda_2^2 \omega^2; \hspace{1cm} \delta_3^2 = \lambda_3^2 \omega^2$$  \hspace{1cm} (57)$$

and for medium $M_1$, we take

$$\{ \phi^f, \phi^f, p \} = \{ 1, m_1, m_2 \} \left[ A_{01} \exp \left[ ik_1 \left( x \sin \theta_0 - z \cos \theta_0 \right) + i \omega \bar{t} \right] + A_1 \exp \left[ ik_1 \left( x \sin \theta_1 + z \cos \theta_1 \right) + i \omega \bar{t} \right] \right]$$  \hspace{1cm} (58)$$

© 2018 IAU, Arak Branch
\[ \{\psi^s, \psi^r\} = \{1, m_3\} \left[ B_{0i} \exp\left\{ik_z (x \sin \theta_0 - z \cos \theta_0) + i \omega t\right\} + A_z \exp\left\{ik_z (x \sin \theta_z + z \cos \theta_z) + i \omega t\right\} \right] \] (59)

where,

\[ m_1 = \frac{\eta^s}{\eta^r}; \quad m_2 = \left[ \frac{\eta^s \omega^2 \rho^s - i \omega S_v}{(\eta^r)^2} \right]; \quad m_3 = \frac{i \omega S_v}{i \omega S_v - \alpha_z^2 \rho^r} \] (60)

and \( B_1, B_2, B_3 \) are amplitudes of transmitted P-wave, transmitted coupled transverse and transmitted micro-rotation waves respectively. Also \( A_{0i} \) or \( B_{0i} \), \( A_1 \) and \( A_2 \) are amplitudes of incident P-wave or SV-wave, reflected P-wave and reflected SV-wave respectively and to be determined from boundary conditions.

5 BOUNDARY CONDITIONS

Boundary conditions appropriate here are the continuity of displacement, micro rotation and stresses at the interface separating medium \( M_1 \) and \( M_2 \). These boundary conditions at \( z = 0 \) can be written in mathematical form as:

\[ t_{zs} = t_{zs}^x - p; \quad t_{zs} = t_{zs}^s; \quad m_{zy} = 0; \quad t_{zs}^s = K_s \left( w - w^s \right); \quad t_{zs} = K_t \left( u - u^s \right) \] (61)

where \( K_s \) and \( K_t \) are normal and tangential stiffness coefficient.

In order to satisfy the boundary conditions, the extension of the Snell’s law will be

\[ \frac{\sin \theta_0}{\nu_0} = \frac{\sin \theta_1}{\nu_1} = \frac{\sin \theta_2}{\nu_2} = \frac{\sin \theta_3}{\nu_3} = \frac{\sin \theta_3}{\nu_3} \] (62)

where, \( \nu_2 = \frac{1}{\lambda_2} \); \( \nu_3 = \frac{1}{\lambda_3} \). For longitudinal wave,

\[ \nu_0 = \nu_1, \quad \theta_0 = \theta_1 \] (63)

For transverse wave,

\[ \nu_0 = \nu_2, \quad \theta_0 = \theta_2 \] (64)

Also

\[ \delta y_1 = \delta y_2 \lambda_1^{-1} = \delta y_3 \lambda_3^{-1} = k y_1 = k y_2 = \omega, \quad z = 0 \] (65)

Making the use of potentials given by Eqs. (52)-(54) and (58)-(59) in the boundary conditions given by Eq. (61) and using (62)-(65), we get a system of five non-homogeneous equations which can be written as:

\[ \sum_{j=1}^{5} a_i Z_j = Y_i, \quad (i = 1, 2, 3, 4, 5) \] (66)

where
where $B_0 = A_{i_0}$ or $B_{0j}$ is amplitude of incident $P$-wave or $SV$-wave respectively.

Also $Z_1$ to $Z_5$ are the amplitude ratios of transmitted longitudinal wave, transmitted coupled-wave at an angle $\theta_i$, transmitted coupled-wave at an angle $\theta_i$, reflected $P$-wave and reflected $SV$-wave, respectively. Also $a_{ij}$ and $Y_i$ in non-dimensional form are as:

$$a_{11} = \frac{-\lambda \delta^2 - (2\mu + \kappa)(\delta^2 \cos^2 \theta_i)}{\mu \delta_i^2}; \quad a_{12} = \frac{(2\mu + \kappa) \delta^2 \sin \theta_i \cos \theta_i}{\mu \delta_i^2}; \quad a_{13} = \frac{(2\mu + \kappa) \delta^2 \sin \theta_i \cos \theta_i}{\mu \delta_i^2};$$

$$a_{14} = \frac{k_2 \left( \lambda^2 + 2\mu \delta^2 \cos^2 \theta_i \right) + m_2}{\mu \delta_i^2}; \quad a_{15} = \frac{-2\mu \delta^2 \sin \theta_i \cos \theta_i}{\mu \delta_i^2}; \quad a_{22} = \frac{(2\mu + \kappa) \delta^2 \sin \theta_i \cos \theta_i}{\mu \delta_i^2};$$

$$a_{23} = \frac{\mu \delta^2 \cos 2\theta_i + \kappa \delta^2 \cos \theta_i \cos \theta_i - \kappa \delta^2 \cos \theta_i \cos \theta_i}{\mu \delta_i^2}; \quad a_{24} = \frac{\mu \delta^2 \cos 2\theta_i + \kappa \delta^2 \cos \theta_i \cos \theta_i - \kappa \delta^2 \cos \theta_i \cos \theta_i}{\mu \delta_i^2};$$

$$a_{25} = \frac{\mu \delta^2 \cos 2\theta_i}{\mu \delta_i^2}; \quad a_{31} = 0; \quad a_{32} = \cos \theta_i; \quad a_{33} = \frac{\delta E \cos \theta_i}{\delta_i^2}; \quad a_{34} = 0; \quad a_{35} = 0;$$

$$a_{41} = \frac{\lambda \delta^2 + (2\mu + \kappa) \delta^2 \cos^2 \theta_i}{k \delta_i^2}; \quad a_{42} = \frac{-2\mu \delta^2 \sin \theta_i \cos \theta_i \cos \theta_i}{k \delta_i^2}; \quad a_{43} = \frac{-2\mu \delta^2 \sin \theta_i \cos \theta_i \cos \theta_i}{k \delta_i^2};$$

$$a_{44} = \frac{\delta E \cos \theta_i}{\delta_i^2}; \quad a_{45} = \frac{-ik \cos \theta_i}{\delta_i^2}; \quad a_{51} = \frac{-2\mu \delta^2 \sin \theta_i \cos \theta_i \cos \theta_i}{k \delta_i^2};$$

$$a_{52} = \frac{\kappa \delta^2 \cos \theta_i \cos \theta_i}{k \delta_i^2}; \quad a_{53} = \frac{-2\mu \delta^2 \sin \theta_i \cos \theta_i \cos \theta_i}{k \delta_i^2};$$

$$a_{54} = \frac{\delta E \cos \theta_i}{\delta_i^2}; \quad a_{55} = \frac{\delta E \cos \theta_i}{\delta_i^2}.$$

For incident $P$-wave

$$Y_1 = -a_{14}; \quad Y_2 = a_{24}; \quad Y_3 = a_{34}; \quad Y_4 = a_{44}; \quad Y_5 = -a_{54}.$$  \hfill (68)

For incident $SV$ wave

$$Y_1 = a_{15}; \quad Y_2 = -a_{25}; \quad Y_3 = a_{35}; \quad Y_4 = -a_{45}; \quad Y_5 = a_{55}.$$  \hfill (68)

6 PARTICULAR CASE: WELDED CONTACT ($K_n \to \infty, K_s \to \infty$)

Again in this case, a system of five non-homogeneous equations is obtained as in Eq. (68) with some $a_{ij}$ changed as:

$$a_{41} = \frac{i \delta \cos \theta_i}{\delta_i^2}; \quad a_{42} = \frac{-i \delta \sin \theta_i}{\delta_i^2}; \quad a_{43} = \frac{-i \delta \sin \theta_i}{\delta_i^2}; \quad a_{44} = \frac{-i \delta \cos \theta_i}{\delta_i^2}; \quad a_{45} = \frac{-i \delta \sin \theta_i}{\delta_i^2};$$

$$a_{53} = \frac{-i \delta \cos \theta_i}{\delta_i^2}.$$  \hfill (69)
7 SPECIAL CASE

If pores are absent or gas is filled in the pores then $\rho^s$ is very small as compared to $\rho^e$ and can be neglected, so the relation (41) gives us

$$C = \sqrt{\frac{\lambda^e + 2\mu^e}{\rho^e}}$$  \hspace{1cm} (70)

In this situation the problem reduces to the problem to empty porous solid half-space lying over micro polar elastic solid half-space.

8 NUMERICAL RESULTS AND DISCUSSION

In order to study in more detail, the behavior of various amplitude ratios, we have computed them numerically for a particular model for which the values of relevant elastic parameters are as follow:

In medium $M_1$, the physical constants for fluid saturated incompressible porous medium are taken from de Boer, Ehlers and Liu [9] as:

$\eta^s = 0.67$, $\eta^e = 0.33$, $\rho^s = 1.34$ Mg/m$^3$, $\rho^e = 0.33$ Mg/m$^3$, $\lambda^e = 5.5833$ MN/m$^2$, $K^e = 0.01$ m/s, $\gamma^{fr} = 10.00$ KN/m$^3$, $\mu^e = 8.3750$ N/m$^2$

In medium $M_2$, the physical constants for micro polar elastic solid are taken from Gauthier [12] as:

$\lambda = 7.59 \times 10^9$ N/m$^2$, $\mu = 1.89 \times 10^{10}$ N/m$^2$, $\kappa = 1.49 \times 10^8$ N/m$^2$, $\rho = 2.19 \times 10^3$ kg/m$^3$, $\gamma = 2.68 \times 10^4$ N, $j = 1.96 \times 10^{-6}$ m$^2$, $\omega_0 = 200$ \hspace{1cm} (71)

To calculate the modulus of amplitude ratios of various reflected and transmitted waves for the particular model and to depict graphically, a computer program in MATLAB has been developed. The amplitude ratios are computed for the angle of incidence varying from 0° to 90°. The variation of modulus of amplitude ratios $Z_{ij}$ with angle of emergence $\theta_i$ of longitudinal P-wave or transverse SV wave are shown in Figs. (2)-(31). In Figs. (2)-(21) dotted lines show the variations of amplitude ratios $|Z_{ij}|$ when medium-$M_1$ is incompressible fluid saturated porous medium (FS) and medium-$M_{11}$ is micro polar elastic solid and boundary between half-space is imperfect whereas solid lines show the variations of amplitude ratios when contact between half-spaces is welded. In Figs. (2) - (6), there is P-wave incident whereas in Figs. (7) - (11), SV wave is incident. In Figs. (12) - (16), there is P-wave incident and incompressible fluid saturated porous medium (FS) becomes empty porous solid (EPS) whereas in Figs. (17) - (21), SV wave is incident and medium-$M_1$ is empty porous solid. The nature of dependence of modulus of amplitude ratios $Z_{ij}$ on P-wave or SV is shown in Figs. (22)-(31). The nature of dependence of modulus of amplitude ratios $Z_{ij}$ is different for different reflected and transmitted waves.

8.1 Longitudinal wave incidence

The Figs. (2)-(6), show the variations of the modulus of amplitude ratios of reflected P-wave i.e. $|Z_{ij}|$, reflected SV wave i.e. $|Z_{ij}|$, transmitted P-wave i.e. $|Z_{ij}|$, transmitted CDI-wave i.e. $|Z_{ij}|$, and transmitted CDII-wave i.e. $|Z_{ij}|$, with angle of incidence of incident P-wave. In Figs. (2) -(6), the effect of welded contact is significant to general stiffness case (imperfect interface) and is clear from the graphs. Also, in Figs. (12) - (16), in case of empty porous solid, the effect of stiffness is clear. In these figures, the modulus value of amplitudes ratios for imperfect interface
is small than all other cases except in Figs. (5) and (15)-(16). The effect of fluid filled in pores of fluid saturated porous medium is evident after comparing the corresponding Figs. (2)-(6) and (12)-(16).

Variation of the amplitude ratio $|Z_i|$, $i=1, 2, \ldots, 5$ with angle of incidence of incident $P$-wave.
8.2 Transverse wave incidence

The Figs. (7) - (11), show the variation of the modulus of amplitude ratios of reflected P-wave, reflected SV wave, transmitted P-wave, transmitted CDI-wave, and transmitted CDII-wave, with angle of incidence of incident SV-wave. In the Figs. (7) - (11), the amplitude ratios are small for imperfect boundary in comparison to welded contact except in Fig. (11). Also, in Figs. (17) - (21), in case of empty porous solid, the effect of stiffness is clear and amplitude ratios are small for imperfect interface in comparison to welded contact. After comparing the corresponding Figs. (7) - (11) and (17) - (21), the effect of fluid filled in pores of fluid saturated porous medium is clear.

8.3 P-wave or SV wave incidence

Figs. (22) - (26) depicts the effect of incident longitudinal and incident transverse wave on the variation of amplitude ratios. From these figures it is very clear that the amplitude ratios depend on incident wave. Also, the amplitude ratios are small for incident P-wave in comparison to SV wave except for modulus of amplitude ratio of reflected P-wave i.e. $|Z_4|$. Effect of incident longitudinal or incident transverse wave on the variation of amplitude ratios in case of empty porous solid is shown in Figs. (27) - (31). In these figures, the modulus of amplitude ratios for transmitted waves, are large in case of SV wave incidence and small for reflected waves.

CONCLUSIONS

In conclusion, a mathematical study of reflection and transmission coefficient at an imperfect interface separating micro polar elastic solid half-space and fluid saturated incompressible porous solid half space is made when longitudinal wave or transverse wave is incident. It is observed that

1. The amplitudes ratios of various reflected and transmitted waves are found to be complex valued.
2. The modulus of amplitudes ratios of various reflected and transmitted waves depend on the angle of incidence of the incident wave and material properties of half-spaces.
3. The effect of fluid filled in the pores of incompressible fluid saturated porous medium is significant on the amplitudes ratios.
4. The effect of incident wave is significant on amplitude ratios. All the amplitudes ratios are found to depend on incident waves.
5. The effect of stiffness is significant either longitudinal wave is incident or transverse wave is incident.
The model presented in this paper is one of the more realistic forms of the Earth models. The present theoretical results may provide useful information for experimental scientists/researchers/seismologists working in the area of wave propagation in micropolar elastic solid and fluid saturated incompressible porous solid.
